

# Mammalian Fuel Metabolism: Integration and Regulation

# Organ specialization

Glycolysis

Gluconeogenesis

Glycogen degradation and synthesis

Fatty acid synthesis and degradation

The citric acid cycle

Oxidative phosphorylation

Amino acid synthesis and degradation

## Two key compounds

Acetyl-CoA

Pyruvate

Need based control depending on organs

Figure 21-1 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

# The metabolic relationships among brain, adipose tissue, muscle, liver, and kidney

Figure 21-2 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

# 1. Brain

Constitutes only ~2% of the adult body mass,

but is responsible for ~20% of its resting oxygen consumption

(Na<sup>+</sup>-K<sup>+</sup>)-ATPase: maintain membrane potential for nerve impulse transmission

Require a steady supply of glucose

Glucose is the primary fuel

Depends on ketone bodies under extended fasting condition

Less than ~5 mM causes fatal problems

Hypoglycemia in Type 1 diabetes mellitus

Hypoglycemia-Associated Autonomic Failure (HFA)

**Table 1** Percentage of individuals with T1DM showing deficient responses in each of the major hypoglycaemic counter-regulatory hormones over time. From Mokan *et al.* [81]

Duration of diabetes	Glucagon (%)	Epinephrine (%)	Cortisol (%)	GH (%)
< 1 year	27	9	0	0
1–5 years	75	25	0	0
5–10 years	100	44	11	11
> 10 years	92	66	25	25

## 2. Muscle

Major fuels: glycogen, fatty acids, ketone bodies

Glycogen (1-2% of mass) mobilize more rapidly and can be metabolized anaerobically

Muscle carbohydrate serves only muscle

Glycogen is converted to G-6-P

Synthesize glycogen but not glucose

### Source of ATP during exercise in human

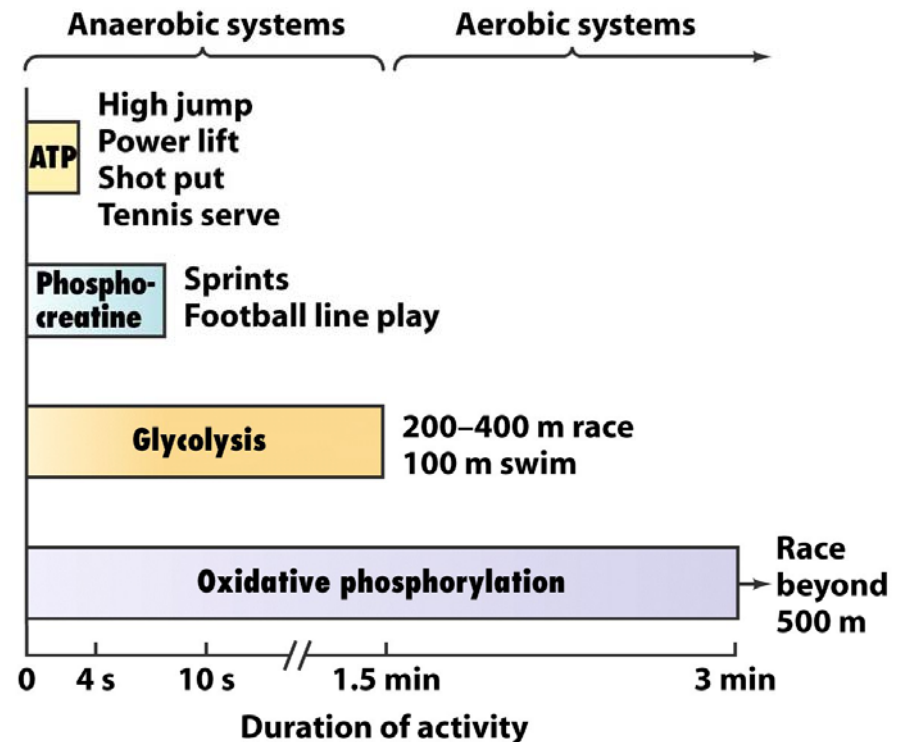

Figure 21-3 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

## Muscle types

Skeletal muscle: voluntary muscle

Two types: slow twitch, fast twitch

Smooth muscle: involuntary muscle within the walls of organs except heart

Cardiac muscle: involuntary muscle in heart

## 3. Heart

Largely aerobic

Continuous operation

Rich in mitochondria (up to 40% of cytoplasm)

Fatty acids are resting heart's fuel but depends on glucose during heavy work

Angina (heart pain) due to an insufficient oxygen supply

**Ranolazine**

Fatty acid oxidation inhibitor,  
making heart muscle depends on glucose

## 4. Adipose tissue

Fatty acid mobilization

Triacylglycerol by hormone-sensitive lipase

Metabolic need to fatty acids is signaled by decrease in [glucose]  
[glycerol-3-P] determines the direction

## 5. Liver

Central metabolic clearinghouse

Portal vein from intestine: all the nutrients except fatty acids

# Liver

Portal vein

Hepatic veins

Pancreatic veins

<http://www.siumed.edu/~dking2/erg/liver.htm>

## HEPATIC LOBULE

## Liver Lobule

## Detail of Lobule

# Glucokinase in liver

Liver acts as a blood glucose “buffer”

Blood glucose to G-6-P by glucokinase (a liver isozyme of hexokinase)

A monomeric enzyme but has sigmoidal kinetic behavior

Subject to metabolic control

Glucokinase regulatory protein: a competitive inhibitor in the presence of F6P

overcome by F1P: only available from dietary sources and signal the uptake of dietary glucose

Glucokinase is the  $\beta$ -cell's glucose sensor

## Metabolic fate of glucose-6-P in liver (at the crossroads)

Figure 21-5. Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

### The liver can synthesize and degrade triacylglycerols

When the demand for metabolic fuels is high

Fatty acids to acetyl-CoA and then to ketone bodies for transport

Lack 3-ketoacyl-CoA transferase, which convert ketone bodies to acetyl-CoA

When the demand for metabolic fuels is low

Fatty acids to triacylglycerol and transported as VLDL

### Amino acids are metabolic fuels

After feeding, dietary amino acids are completely oxidized or converted to glucose or ketone bodies

During a fast, muscle protein amino acids to glucose

# 6. Kidney

Filters urea and other waste products from the blood

Recovers important metabolites such as glucose

Maintains homeostasis

Acid-base balance: the blood's pH

By regenerating bicarbonate

By excreting excess  $H^+$

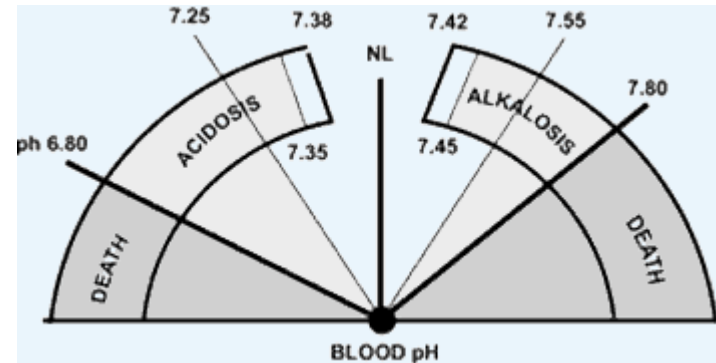

Blood pressure

Plasma volume

Gluconeogenesis from  $\alpha$ -ketoglutarate

50% of the body's glucose

depends on kidney during starvation

## ACID-BASE BALANCING BY THE KIDNEY

- ♦ The response of the kidney to acid-base imbalances is governed by the relative magnitudes of **proton secretion** and **HCO<sub>3</sub> filtration** because these two factors affect the rates of acid and alkali excretion.
- ♦ If  $P_{CO_2}$  rises, proton secretion becomes dominant and the kidney excretes acid, raising blood pH.
- ♦ If  $[HCO_3]_p$  rises, HCO<sub>3</sub> filtration increases and the kidney excretes alkali, reducing blood pH.

## METABOLIC ALKALOSIS

Figure 5: Diagnosis using Serum Acid-Base Values:

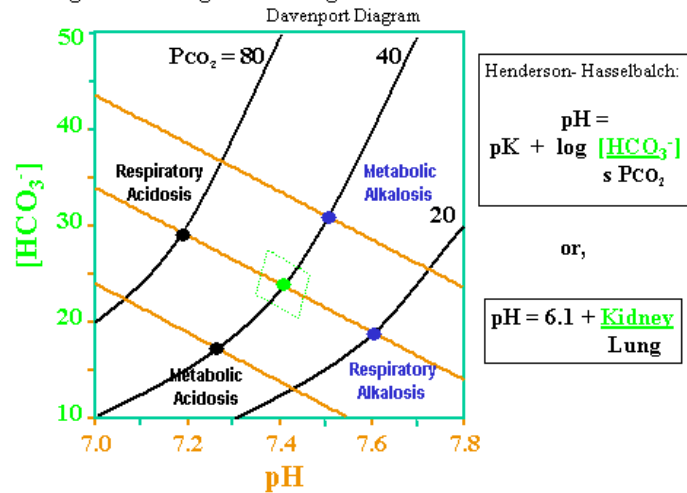

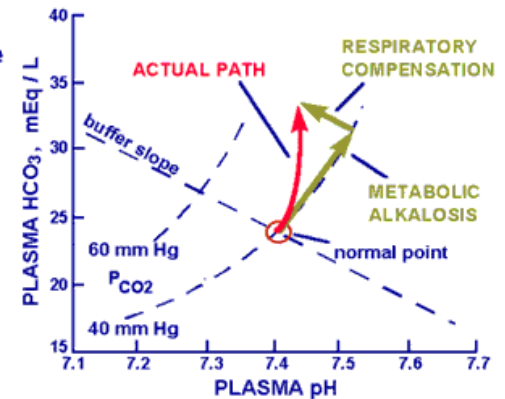

Figure 6: Primary Acid-Base Disturbances

- The addition of alkali to the blood or the loss of acid causes the blood pH and  $[\text{HCO}_3^-]_p$  to rise.
- The respiratory response to the high pH is hypoventilation. The rise in  $\text{CO}_2$  titrates the blood buffers to a lower pH and a further small increase in  $[\text{HCO}_3^-]_p$ .

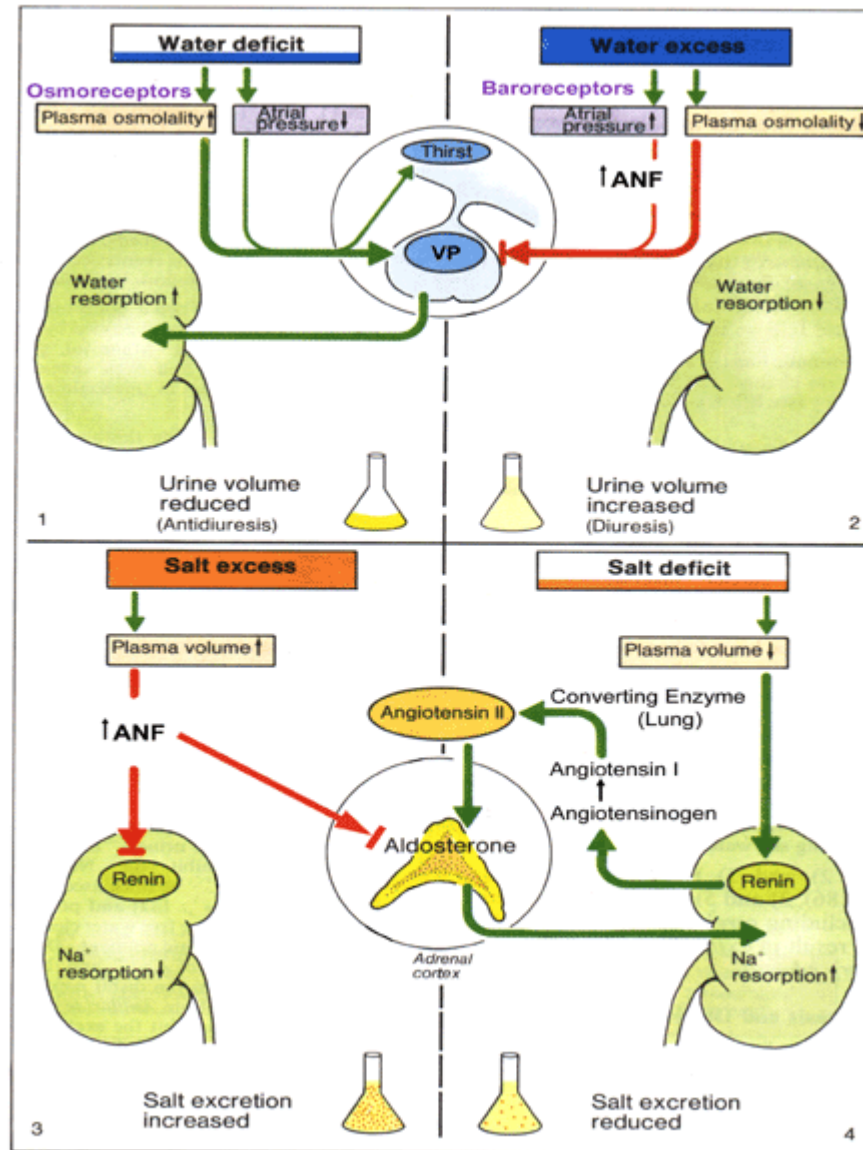

## RESPIRATORY ACIDOSIS

- Hypoventilation causes the retention of acid ( $\text{CO}_2$ ) in the blood.
- $$\text{CO}_2 + \text{H}_2\text{O} \rightarrow \text{H}_2\text{CO}_3$$
- $$\text{H}^+ + \text{HCO}_3^-$$
- The protons titrate the blood buffers to a lower pH and  $\text{HCO}_3^-$  tends to accumulate in the blood.

## Salt and Water Homeostasis

(Modified from Despopoulos & Silbernagl, *Color Atlas of Physiology*, 3rd Ed, Thieme inc.: New York, 1986.)

ANF: atrial natriuretic factor  
VP: vasopressin

# Interorgan metabolic pathways

## The Cori cycle

resynthesis of glucose from lactate  
oxygen debt: ?

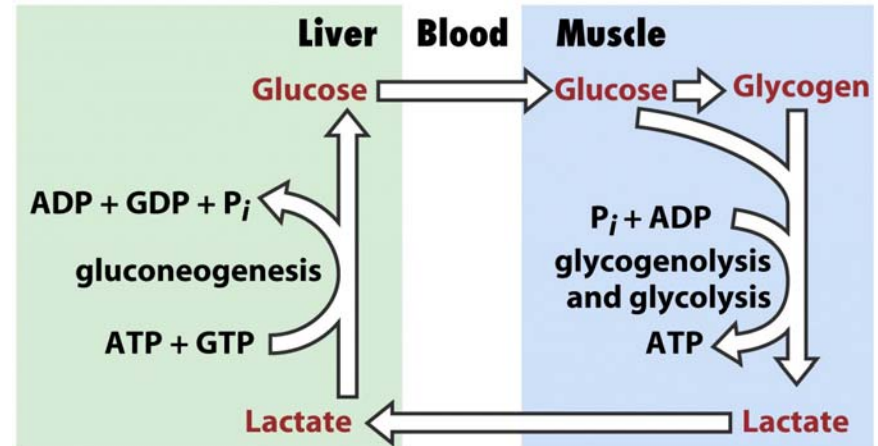

Figure 21-6 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

## The glucose-alanine cycle

transport of nitrogen from muscle to liver

© 2006 John Wiley & Sons

Figure 21-7 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

# Hormonal control of fuel metabolism

Hormones: synthesis & release from endocrine glands

Maintain homeostasis

Response to external stimuli

Control cyclic and developmental programs

## Receptors

Membrane receptor: nonsteroid hormones

Intracellular protein receptor: steroid hormones

©1999 Addison Wesley Longman, Inc.

Figure 21-8 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

Endocrine signaling

# Pancreatic and adrenal hormones

## Pancreas

Digestive enzymes: trypsin, Rnase A,  $\alpha$ -amylase, phospholipase A2

Islets of Langerhans:  $\alpha$ -cells,  $\beta$ -cells

## Pancreatic islet cells

Figure 21-9 Fundamentals of Biochemistry, 2/e

## Adrenal glands

Hormone release in response to neuronal signals

Medulla: an extension of the nervous system

Cortex: synthesizes and secretes hormones

Steroid hormones:

- glucocorticoids (e.g. cortisol): raising blood glucose

- mineralocorticoids (e.g. aldosterone): mineral metabolism

- androgens (e.g. testosterone, androgen):

Catecholamine: norepinephrine, epinephrine

Figure 1: Kidneys and Adrenal Glands

Figure 2: Adrenal Gland Cross Sections

# Insulin release triggered by glucose

Normal blood glucose: 3.6-5.8 mM

$\beta$ -cells are sensitive to glucose at 5.5.-6.0 mM

Passive transport of glucose (GLUT2)

Glucokinase is a glucose sensor

The overall level of the  $\beta$ -cell's respiratory activity regulates insulin synthesis and secretion

## Glucose transporters

Name	Tissue location	$K_m$	Comments
GLUT1	All mammalian tissues	1 mM	Basal glucose uptake
GLUT2	Liver and pancreatic $\beta$ cells	15–20 mM	In the pancreas, plays a role in regulation of insulin In the liver, removes excess glucose from the blood
GLUT3	All mammalian tissues	1 mM	Basal glucose uptake
GLUT4	Muscle and fat cells	5 mM	Amount in muscle plasma membrane increases with endurance training
GLUT5	Small intestine	—	Primarily a fructose transporter

# Glucose transporter & receptor

[http://en.wikipedia.org/wiki/Glucose\\_transporter](http://en.wikipedia.org/wiki/Glucose_transporter)

## Insulin binding to muscle and adipose tissue

GLUT4: insulin-sensitive glucose transporter

## Insulin binding to brain

Constitutive expression of insulin-insensitive glucose transporter

## Insulin binding to liver

Lacks GLUT4

Receptor binding: inactivation of phosphorylase kinase & activation of glycogen synthase  
control gene expression

**Table 21-1 Hormonal Effects on Fuel Metabolism**

Tissue	Insulin	Glucagon	Epinephrine
Muscle	↑ Glucose uptake ↑ Glycogen synthesis	No effect	↑ Glycogenolysis
Adipose tissue	↑ Glucose uptake ↑ Lipogenesis ↓ Lipolysis	↑ Lipolysis	↑ Lipolysis
Liver	↑ Glycogen synthesis ↑ Lipogenesis ↓ Gluconeogenesis	↓ Glycogen synthesis ↑ Glycogenolysis	↓ Glycogen synthesis ↑ Glycogenolysis ↑ Gluconeogenesis

## Insulin receptors:

- The receptors for insulin are found on most mammalian cells – action of insulin is mediated through these receptors.
- Impaired action of insulin can result from defects in the receptors or defects in post-receptor events.

( $K_m$  for glucose is 2-5 mM)

Glucose uptake in muscle and fat cells  
(insulin stimulated exocytosis and endocytosis)

Adrenergic receptors:  $\beta$ -adrenergic (cAMP),  $\alpha$ -adrenergic (calcium ion)

# Signal transduction

# Signal transduction

## Receptor mediated cellular response

G protein-coupled receptors (GPCRs)

>1000 different GPCRs in human genome

Alternate conformational changes on ligand binding

Heterotrimeric G proteins

Bind GTP and GDP

Hydrolyze GTP to GDP + Pi

heterogeneous  $\alpha, \beta, \gamma$  subunits (45,37,9 kD)

## Bovine rhodopsin

cytoplasmic

Figure 21-12 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

## Heterotrimeric G protein

Figure 21-13 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

### Accessory proteins

GTPase-activating protein (GAP): >2000-fold rate enhancement of GTP hydrolysis

Guanine nucleotide exchange factor (GEF): induces GDP release

### Effector proteins: adenylate cyclase

Stimulatory G protein,  $G_s\alpha$

Inhibitory G protein:  $G_i\alpha$

A variety of mammalian G proteins (20  $\alpha$  subunits, 6  $\beta$  subunits, 12  $\gamma$  subunits)

Signal amplification

# Adenylate cyclase

$\text{ATP} \rightarrow \text{cAMP} + \text{PP}_i$

Tissue specific 10 isoforms in mammals

Differ in their regulatory properties

$\text{NM}_1\text{C}_{1a}\text{C}_{1b}\text{M}_2\text{C}_{2a}\text{C}_{2b}$  sequence

C1a+C2a: catalytic core

C1b and C1a+C2a: bind regulatory molecules

Other regulators:  $\text{Ca}^{2+}$ , calmodulin, PKA, PKC

A variety of stimulus determines cAMP levels

## Mammalian adenylate cyclase

Figure 21-14 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

## The adenylate cyclase signaling system

# Drug and toxins that affect cell signaling

Methylated purine derivatives  
Increase cAMP

Cholera toxin: AB<sub>5</sub>

~195 residue proteolytic fragment of A subunit

Transfer of ADP-ribose from NAD<sup>+</sup> to Gsα

Gsα activates adenylate cyclase but can't hydrolyze GTP

~100 fold increase of cAMP

Pertussis toxin

Homolog of cholera toxin

ADP-ribosylation of Giα

No exchange of GDP with GTP

Continued activation of adenylate cyclase

R = CH<sub>3</sub> X = CH<sub>3</sub> Caffeine (1,3,7-trimethylxanthine)  
R = H X = CH<sub>3</sub> Theophylline (1,3-dimethylxanthine)  
R = CH<sub>3</sub> X = H Theobromine (1,7-dimethylxanthine)

Figure 21-17b Fundamentals of Biochemistry, 2/e

## The main targets of the insulin RTK

Insulin receptor substrates 1 (IRS-1)  
Insulin receptor substrates 2 (IRS-2)

protein tyrosine phosphatases

Interact with another sets of proteins

Proteins having SH2 (Src homology 2) domains

High affinity to phospho-Tyr

G protein activation  
Phosphorylation  
Dephosphorylation

## Growth factor RTK cascade

Grb2 protein (mammalian)

SH2 domain

2 SH3 domains (50~75 residues, binding Pro-rich sequences)

Sos protein (containing Pro-rich sequence)

Ras activation (a monomeric G protein)

Raf

MEK (MAP kinase/ERK kinase-activating kinase)/MAP kinase kinase

MAPK (mitogen-activated protein kinase)/ERK(extracellular-signal-regulated kinases)

Activation of transcription factors (Fos, Jun, Myc)

Figure 21-19 Fundamentals of Biochemistry, 2/e

© 2006 John Wiley & Sons

# Oncogenes & cancer

Tumor: masses of cells in uncontrolled growth

Adult cells are largely quiescent

Malignant tumors (cancer): rapid growth, invasive

Benign tumors: slow growth, remain in place

## Oncogenes/protooncogenes

v-src/c-src (60-kD tyrosine kinase)

v-erbB: EGF (epidermal growth factor) receptor lacking EGF-binding domain

v-ras: hydrolyze GTP much more slowly

Box 21-2 Fundamentals of Biochemistry, 2/e

Liver cancer

## Protein tyrosine phosphatases (PTPs)

CX<sub>5</sub>R motif

Membrane bound groups: similar structure to RTKs

Intracellular groups: having SH-2 domain (SHP-2)

## Protein Ser/Thr phosphatases: having binuclear metal ion

PPP family: Fe<sup>2+</sup> (or Fe<sup>3+</sup>) and Zn<sup>2+</sup> (or Mn<sup>2+</sup>) in the catalytic centers

PPM family: two Mn<sup>2+</sup> ions in the catalytic centers

### SHP-2

# Insulin signal transduction

# Anthrax

Protective antigen (PA): binding to receptor

Edema factor (EF): adenylate cyclase (requiring host calmodulin)

Lethal factor (LF): protease of MAPKK family

Box 21-3 figure 1 Fundamentals of Biochemistry, 2/e

Box 21-3 figure 2 Fundamentals of Biochemistry, 2/e

# Disturbances in fuel metabolism

Metabolic homeostasis

Metabolic changes in starvation, diabetes, and obesity

## Dietary glucose

1/3 is converted to glycogen in the liver

A half of the remainder is converted to glycogen in muscle cells

The rest is oxidized for immediate needs

Excess glucose is converted to triacylglycerol in the liver and exported for storage in adipose tissue

**Table 21-2 Fuel Reserves for a Normal 70-kg Man**

Fuel	Mass (kg)	Calories <sup>a</sup>
<b><i>Tissues</i></b>		
Fat (adipose triacylglycerols)	15	141,000
Protein (mainly muscle)	6	24,000
Glycogen (muscle)	0.150	600
Glycogen (liver)	0.075	300
<b><i>Circulating fuels</i></b>		
Glucose (extracellular fluid)	0.020	80
Free fatty acids (plasma)	0.0003	3
Triacylglycerols (plasma)	0.003	30
<b><i>Total</i></b>		<b>166,000</b>

<sup>a</sup>1 (dieter's) Calorie = 1 kcal = 4.184 kJ.

Blood glucose remains constant

Gluconeogenesis supplies glucose during starvation

Muscle protein degradation

Brain adaptation to ketone bodies

### Metabolic interrelationships in the early fasting state (fig. 22.3)

Liver glycogen depletion during fasting in 7 subjects

Figure 21-26 Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

## Metabolic interrelationships in the fasting state (fig. 22.4)

# Diabetes mellitus

Heterogeneous clinical syndrome in which the central feature is a chronic elevation of the blood glucose concentration - this results in a range of pathologies.

Due to a deficiency of insulin (absolute) or a resistance to insulin (relative).

type I: insulin-dependent (juvenile-onset diabetes mellitus)

type II: non-insulin-dependent (maturity-onset diabetes mellitus)

The chronic hyperglycemia is associated with long term tissue damage, especially the blood vessels, nerves, heart, kidneys and eyes.

[http://www.latrobe.edu.au/podiatry/diabetesresources/diabetes\\_lecture\\_1.htm](http://www.latrobe.edu.au/podiatry/diabetesresources/diabetes_lecture_1.htm)

Figure 21-27 Fundamentals of Biochemistry, 2/e

Diabetic cataract

## NIDDM: insulin resistant

insulin receptor or signal transduction

increased insulin production

diminished  $\beta$  cell response

increased blood glucose

Overeating suppresses the synthesis of insulin receptors

Obesity causes

- elevated blood conc of free fatty acids
- decreased insulin signal transduction

Drugs decreasing insulin resistance by either

- decreasing glucose release by the liver (metformin)
- or increasing insulin-stimulated glucose disposal in muscle (TZD)
  - they target mito Complex I, thereby decreasing liver gluconeogenesis and increasing muscle glucose utilization

**Metformin**

**A thiazolidinedione (TZD)**

# Obesity

A chronic imbalance between fat and carbohydrate consumption and utilization  
Increases the mass of adipose tissue  
through an increase in the number of adipocytes or their size

## Overeating mouse (*ob/ob*)

lack leptin polypeptide produced by adipocytes  
satiety signal to the brain: decrease food intake & increase metabolism

## Not identical to human

increased fat body, increased leptin  
probably due to decreased leptin receptor

Figure 21-29 Fundamentals of Biochemistry, 2/e

# Neuropeptide Y

Decreased leptin leads to high conc of neuropeptide Y from hypothalamus  
Stimulates appetite and leads to fat accumulation

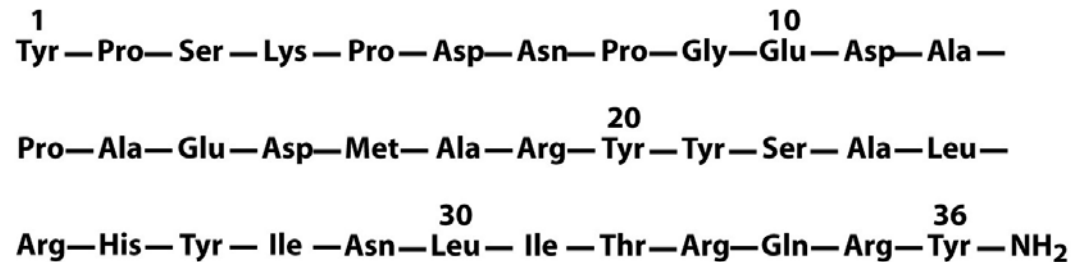

Figure 21-30 Fundamentals of Biochemistry, 2/e

**Neuropeptide Y**  
(The C-terminal carboxyl is amidated)

Unnumbered figure pg 783a Fundamentals of Biochemistry, 2/e  
© 2006 John Wiley & Sons

Fuel metabolism, body weight, and appetite are linked

Insulin receptors in the hypothalamus  
inhibit neuropeptide Y secretion

Ghrelin

appetite-stimulating peptide secreted by the empty stomach  
most likely a short-term appetite control system (increase before meal & decrease just afterward)  
boost levels of neuropeptide Y

Gly—Ser— X —Phe—Leu—Ser—Pro—Glu—His—Gln—<sup>10</sup>

Arg—Val—Gln—Gln—Arg—Lys—Glu—Ser—Lys—Lys—<sup>20</sup>

Pro—Pro—Ala—Lys—Leu—Gln—Pro—Arg<sup>28</sup>

**Ghrelin**

**(X = Ser modified with *n*-octanoic acid)**

## PYY3-36

Appetite suppressing hormone from gastrointestinal tract  
Decrease food intake by inhibiting neuropeptide Y secretion

## Resistin

108-residue polypeptide from adipocyte  
Block the action of insulin on adipocytes
